

Image Primitives and Correspondence

Image

Brightness values

$$I(x,y)$$

Image Features

Local, meaningful, detectable parts of the image.

- Edge detection
- Line detection
- Corner detection

Motivation

- Information content high
- Invariant to change of view point, illumination
- Reduces computational burden
- Uniqueness
- Can be tuned to a task at hand

Filtering and Image Features

Given a noisy image

How do we reduce noise ?

How do we find useful features ?

Today:

- Filtering
- Point-wise operations
- Edge detection

Moving average

- Let's replace each pixel with a *weighted* average of its neighborhood
- The weights are called the *filter kernel*
- What are the weights for the average of a 3x3 neighborhood?

$$\frac{1}{9}$$

1	1	1
1	1	1
1	1	1

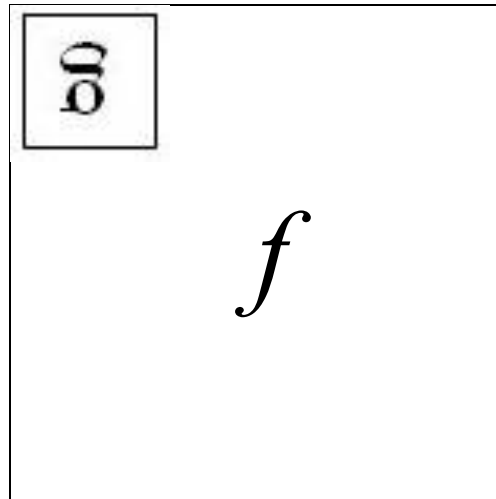

“box filter”

Defining convolution

- Let f be the image and g be the kernel. The output of convolving f with g is denoted $f * g$.

$$(f * g)[m, n] = \sum_{k, l} f[m - k, n - l] g[k, l]$$

Convention:
kernel is “flipped”

- MATLAB functions: [conv2](#), [filter2](#), [imfilter](#)

Details

- What is the size of the output?
- MATLAB: `filter2(g, f, shape)`
 - `shape = 'full'`: output size is sum of sizes of f and g
 - `shape = 'same'`: output size is same as f
 - `shape = 'valid'`: output size is difference of sizes of f and g

Averaging filter 1-D example

$$g[x] = \sum_{k=-\infty}^{\infty} f[k]h[x - k]$$

$$f[x] = [\dots 0, 0, 2, -2, 2, 0, 0, \dots] \quad h[x] = \frac{1}{3}[1, 1, 1]$$

$$h[-1] = \frac{1}{3}, h[0] = \frac{1}{3}, h[1] = \frac{1}{3} \quad \text{and 0 everywhere else}$$

$$f[-1] = -2, f[0] = 2, f[1] = -2$$

Box filter

$$g[x] = \sum_{k=-1}^1 f[k]h[x - k]$$

Ex. cont.

$$g[-1] = f[-1]h[-1 - 1] + f[0]h[-1] + f[1]h[0]$$

$$g[0] = f[-1]h[-1] + f[0]h[0] + f[1]h[1]$$

Averaging filter center pixel weighted more

$$h[x] = [0.25, 0.5, 0.25]$$

Averaging filter

Convolution in 2D

$$g[x, y] = \sum_{k=-\frac{w}{2}}^{\frac{w}{2}} \sum_{l=-\frac{w}{2}}^{\frac{w}{2}} f[k, l]h[x - k, y - l]$$

$$1/9.(10x1 + 0x1 + 2x1 + 9x1 + 10x1 + 9x1 + 11x1 + 9x1 + 99x1) = 1/9.(159) = 17.6667$$

How big should the mask be?

- The bigger the mask,
 - more neighbors contribute.
 - smaller noise variance of the output.
 - bigger noise spread.
 - more blurring.
 - more expensive to compute.
 - In Matlab function **conv**, **conv2**

Example: Smoothing by Averaging

Gaussian Filter

- A particular case of averaging
 - The coefficients are samples of a 1D Gaussian.
 - Gives more weight at the central pixel and less weights to the neighbors.
 - The further away the neighbors, the smaller the weight.

$$g(x) = \frac{1}{\sqrt{2\pi}\sigma} e^{\frac{-x^2}{2\sigma^2}},$$

Sample from the continuous Gaussian

Smoothing with a Gaussian

How big should the mask be?

- The std. dev of the Gaussian σ determines the amount of smoothing.
- The samples should adequately represent a Gaussian
- For a 98.76% of the area, we need

$$m = 5\sigma$$

$$5 \cdot (1/\sigma) \leq 2\pi \Rightarrow \sigma \geq 0.796, m \geq 5$$

5-tap filter

$$g[x] = [0.136, 0.6065, 1.00, 0.606, 0.136]$$

Gaussian filters

- Remove “high-frequency” components from the image (low-pass filter)
- Convolution with self is another Gaussian
 - So can smooth with small- σ kernel, repeat, and get same result as larger- σ kernel would have
 - Convoluting two times with Gaussian kernel with std. dev. σ is same as convoluting once with kernel with std. dev. $\sigma\sqrt{2}$
- *Separable* kernel
 - Factors into product of two 1D Gaussians

Separability of the Gaussian filter

$$\begin{aligned} G_{\sigma}(x, y) &= \frac{1}{2\pi\sigma^2} \exp\left(-\frac{x^2 + y^2}{2\sigma^2}\right) \\ &= \left(\frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{x^2}{2\sigma^2}\right)\right) \left(\frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{y^2}{2\sigma^2}\right)\right) \end{aligned}$$

The 2D Gaussian can be expressed as the product of two functions, one a function of x and the other a function of y

In this case, the two functions are the (identical) 1D Gaussian

Separability example

2D convolution
(center location only)

$$\begin{array}{|c|c|c|} \hline 1 & 2 & 1 \\ \hline 2 & 4 & 2 \\ \hline 1 & 2 & 1 \\ \hline \end{array} * \begin{array}{|c|c|c|} \hline 2 & 3 & 3 \\ \hline 3 & 5 & 5 \\ \hline 4 & 4 & 6 \\ \hline \end{array}$$

The filter factors
into a product of 1D
filters:

$$\begin{array}{|c|c|c|} \hline 1 & 2 & 1 \\ \hline 2 & 4 & 2 \\ \hline 1 & 2 & 1 \\ \hline \end{array} = \begin{array}{|c|} \hline 1 \\ \hline 2 \\ \hline 1 \\ \hline \end{array} \times \begin{array}{|c|c|c|} \hline 1 & 2 & 1 \\ \hline \end{array}$$

Perform convolution
along rows:

$$\begin{array}{|c|c|c|} \hline 1 & 2 & 1 \\ \hline \end{array} * \begin{array}{|c|c|c|} \hline 2 & 3 & 3 \\ \hline 3 & 5 & 5 \\ \hline 4 & 4 & 6 \\ \hline \end{array} = \begin{array}{|c|c|c|} \hline & 11 & \\ \hline & 18 & \\ \hline & 18 & \\ \hline \end{array}$$

Followed by convolution
along the remaining column:

Image Smoothing

- Convolution with a 2D Gaussian filter

$$\tilde{I}(x, y) = I(x, y) * g(x, y) = I(x, y) * g(x) * g(y)$$

- Gaussian filter is separable, convolution can be accomplished as two 1-D convolutions

$$\tilde{I}[x, y] = I[x, y] * g[x, y] = \sum_{k=-\frac{w}{2}}^{\frac{w}{2}} \sum_{l=-\frac{w}{2}}^{\frac{w}{2}} I[k, l]g[x - k]g[y - l]$$

How big should the mask be?

- The bigger the mask,
 - more neighbors contribute.
 - smaller noise variance of the output.
 - bigger noise spread.
 - more blurring.
 - more expensive to compute.

Edges

- They happen at places where the image values exhibit sharp variation

Edge detection (1D)

Edge= sharp variation

Large first derivative

Digital Approximation of 1st derivatives

$$\frac{df(x)}{dx} = \lim_{\Delta x \rightarrow 0} \frac{f(x + \Delta x) - f(x)}{\Delta x}$$

$$\frac{df(x)}{dx} \cong \frac{f(x+1) - f(x-1)}{2}$$

Gaussian and its derivative

$$g(x) = \frac{1}{\sqrt{2\pi}\sigma} e^{\frac{-x^2}{2\sigma^2}}, \quad g'(x) = -\frac{x}{\sigma^2\sqrt{2\pi}\sigma} e^{\frac{-x^2}{2\sigma^2}}.$$

Vertical edges

$$I_x(x, y) = \frac{\partial I}{\partial x}$$

First derivative - one column

Horizontal edges

$$I_y(x, y) = \frac{\partial I}{\partial y}$$

Gradient orientation

- Image Gradient $\nabla I = \left[\frac{\partial I}{\partial x}, \frac{\partial I}{\partial y} \right]$

- Gradient Magnitude

$$m = \sqrt{\left(\frac{\partial I}{\partial x} \right)^2 + \left(\frac{\partial I}{\partial y} \right)^2}$$

- Gradient Orientation

$$\theta = \tan^{-1} \left(\frac{\partial I}{\partial x}, \frac{\partial I}{\partial y} \right)$$

Canny Edge Detector

- Edge detection involves 3 steps:
 - Noise smoothing
 - Edge enhancement
 - Edge localization
- J. Canny formalized these steps to design an *optimal* edge detector
- How to go from derivatives to edges ?

Horizontal edges

Edge Detection

original image

gradient magnitude

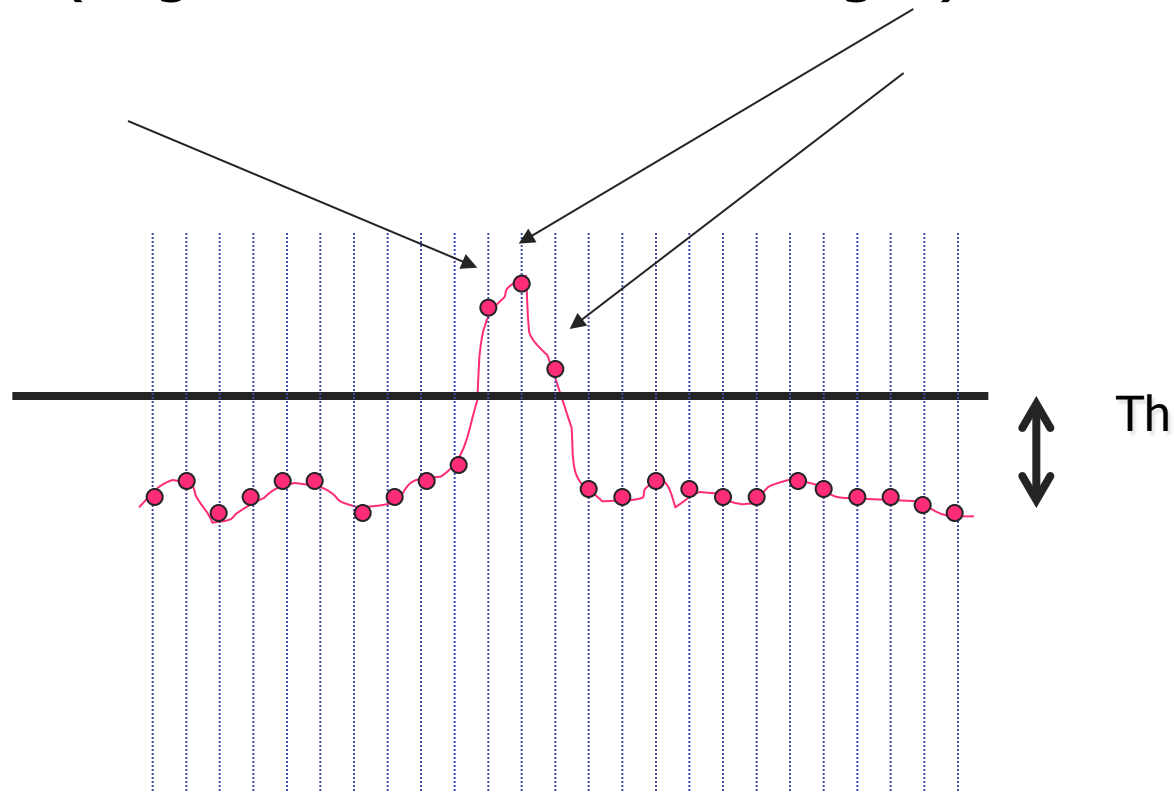

Canny edge detector

- Compute image derivatives
- if gradient magnitude $> \tau$ and the value is a local maximum along gradient direction – pixel is an edge candidate

Algorithm Canny Edge detector

- The input is image I ; G is a zero mean Gaussian filter (std = σ)
 1. $J = I * G$ (smoothing)
 2. For each pixel (i,j) : (edge enhancement)
 - Compute the image gradient
 - $\nabla J(i,j) = (J_x(i,j), J_y(i,j))'$
 - Estimate edge strength
 - $e_s(i,j) = (J_x^2(i,j) + J_y^2(i,j))^{1/2}$
 - Estimate edge orientation
 - $e_o(i,j) = \arctan(J_x(i,j)/J_y(i,j))$
- The output are images E_s - Edge Strength - Magnitude
- and Edge Orientation E_o -

-
- E_s has large values at edges: Find local maxima
 - ... but it also may have wide ridges around the local maxima (large values *around* the edges)

NONMAX_SUPPRESSION

- The inputs are E_s & E_o (outputs of CANNY_ENHANCER)
- Consider 4 directions $D = \{0, 45, 90, 135\}$ wrt x
- For each pixel (i, j) do:
 1. Find the direction $d \in D$ s.t. $d \cong E_o(i, j)$ (normal to the edge)
 2. If $\{E_s(i, j)$ is smaller than at least one of its neigh. along $d\}$
 - $I_N(i, j) = 0$
 - Otherwise, $I_N(i, j) = E_s(i, j)$
- The output is the thinned edge image I_N

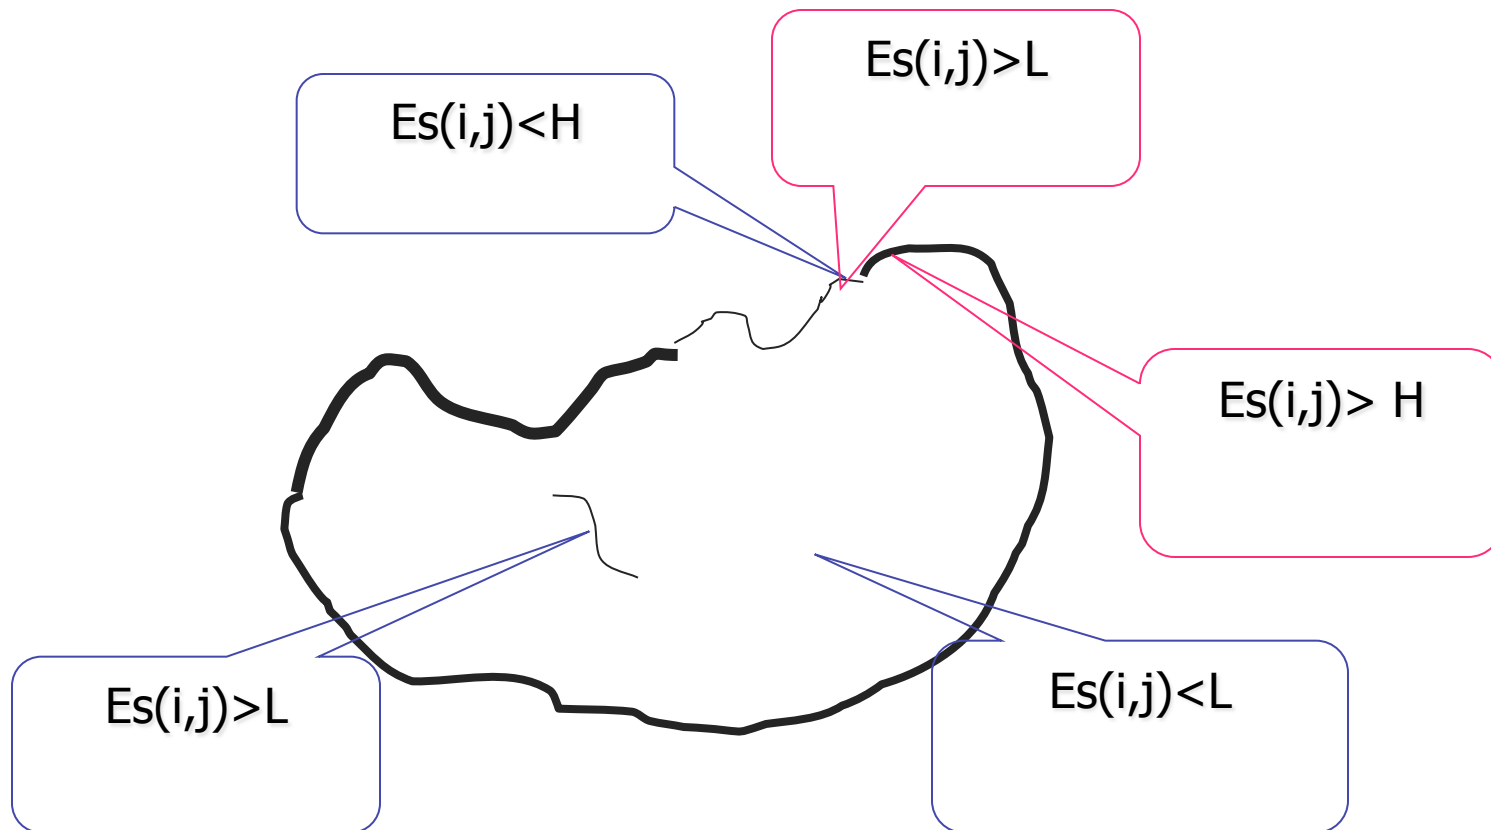

Graphical Interpretation

Thresholding

- Edges are found by thresholding the output of NONMAX_SUPPRESSION
- If the threshold is too high:
 - Very few (none) edges
 - High MISDETECTIONS, many gaps
- If the threshold is too low:
 - Too many (all pixels) edges
 - High FALSE POSITIVES, many extra edges

SOLUTION: Hysteresis Thresholding

Canny Edge Detection (Example)

Filters are templates

- Applying a filter at some point can be seen as taking a dot-product between the image and some vector
- Filtering the image is a set of dot products
- Insight
 - filters look like the effects they are intended to find
 - filters find effects they look like

Appearance using 3D Textons, IJCV 2001

Corner Detection

- A point on a line is hard to match.

Intuition:

- Right at corner, gradient is ill defined.
- Near corner, gradient has two different values.

Formula for Finding Corners

We look at matrix:

Sum over a small region, the hypothetical corner

Gradient with respect to x, times gradient with respect to y

$$C = \begin{bmatrix} \sum I_x^2 & \sum I_x I_y \\ \sum I_x I_y & \sum I_y^2 \end{bmatrix}$$

Matrix is symmetric

First, consider case where:

$$C = \begin{bmatrix} \sum I_x^2 & \sum I_x I_y \\ \sum I_x I_y & \sum I_y^2 \end{bmatrix} = \begin{bmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{bmatrix}$$

This means all gradients in neighborhood are:

$(k,0)$ or $(0,c)$ or $(0,0)$ (or off-diagonals cancel).

What is region like if:

$$\lambda_1 = 0, \lambda_2 \gg 0$$

$$\lambda_1 = 0, \lambda_2 = 0$$

λ_1, λ_2 Are both large

λ_1, λ_2 Are both small

General Case:

From Linear Algebra, it follows that because C is symmetric:

$$C = R^{-1} \begin{bmatrix} \lambda_1 & 0 \\ 0 & \lambda_2 \end{bmatrix} R$$

With R a rotation matrix.

So every case is like one on last slide.

Corner detection

- Filter image.
- Compute magnitude of the gradient everywhere.
- We construct C in a window.
- Use Linear Algebra to find λ_1 and λ_2 .
- If they are both big, we have a corner.

Corner detection

- Filter image.
 - Compute magnitude of the gradient everywhere.
 - We construct C in a window.
 - Use Linear Algebra to find λ_1 and λ_2 .
 - If they are both big, we have a corner.
-
- Key property: in the region around a corner, image gradient has two or more dominant directions
 - Corners are repeatable and distinctive

Corner Detection: Basic Idea

- We should easily recognize the point by looking through a small window
- Shifting a window in *any direction* should give a *large change* in intensity

“flat” region:
no change in all
directions

“edge”:
no change along the
edge direction

“corner”:
significant change in
all directions

Interpreting the eigenvalues

Classification of image points using eigenvalues of C :

Corner response function

$$R = \det(M) - \alpha \text{trace}(M)^2 = \lambda_1 \lambda_2 - \alpha(\lambda_1 + \lambda_2)^2$$

α : constant (0.04 to 0.06)

Plotting ellipses corresponding the the ‘corner’ matrix’
(changing the area over which statistics is averaged)

Harris Corners

Example ($\sigma=0.01$)

Harris Corners

Example ($\sigma=0.001$)

Harris Corners

Harris Corner Detector - Example

Affine intensity change

$$I \rightarrow a I + b$$

- Only derivatives are used => invariance to intensity shift $I \rightarrow I + b$
- Intensity scaling: $I \rightarrow a I$

Partially invariant to affine intensity change

Image translation

- Derivatives and window function are shift-invariant

Corner location is covariant w.r.t. translation

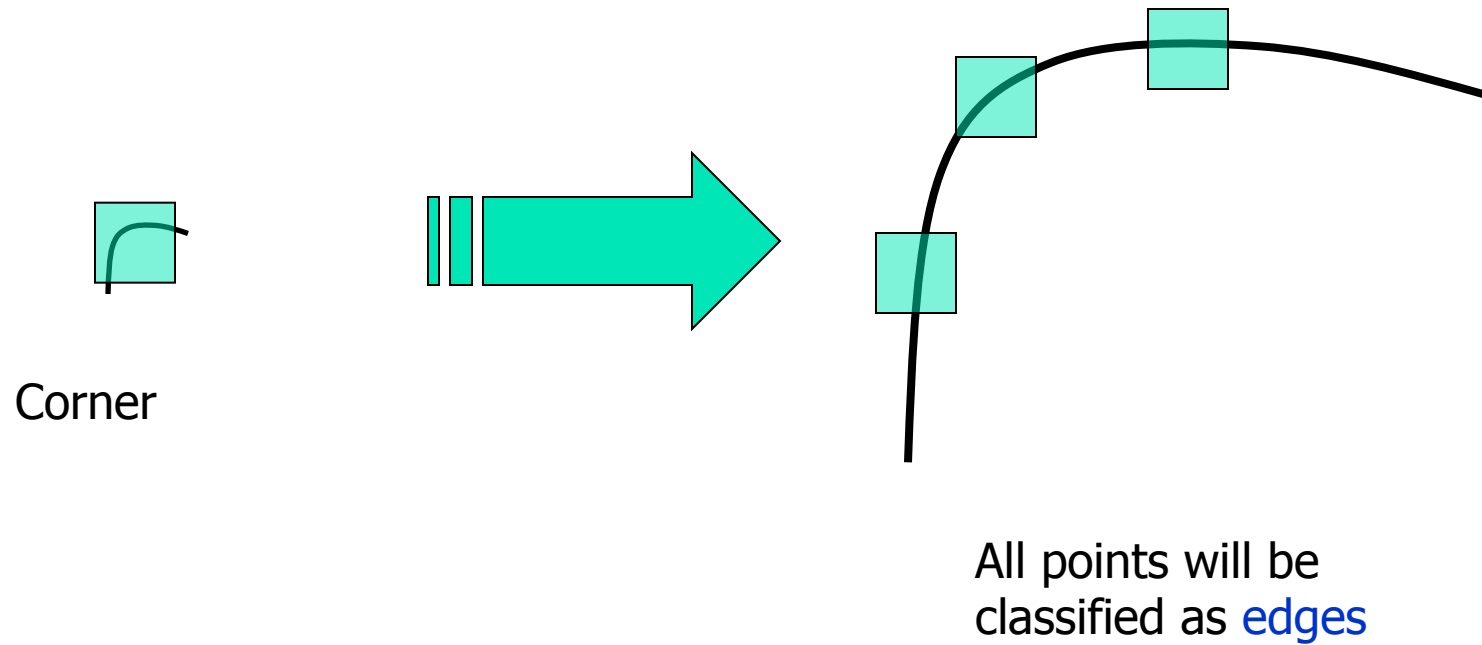

Image rotation

Second moment ellipse rotates but its shape (i.e. eigenvalues) remains the same

Corner location is covariant w.r.t. rotation

Scaling

Corner location is not covariant to scaling!

Scale Invariant Detection

- Consider regions of different size
- Select regions to subtend the same content

Scale Invariant detection

- How to choose the size of the region independently

Scale invariant detection

Idea: design a function over region which remains constant as the size of the region Changes (e.g. average intensity)

Important: this scale invariant region size is found in each image **independently!**

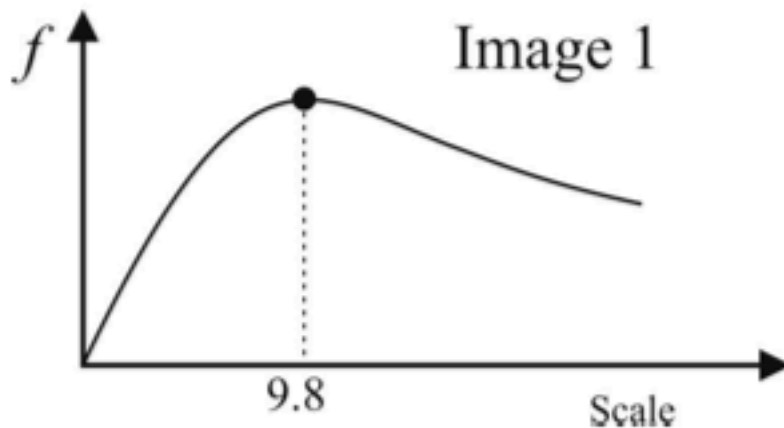

scale = 1/2
→

Scale Invariant detection

- Sharp local intensity changes are good functions for identifying relative scale of the region
- Response of Laplacian of Gaussians (LoG) at a point

Improved Invariance Handling

Want to find

... in here

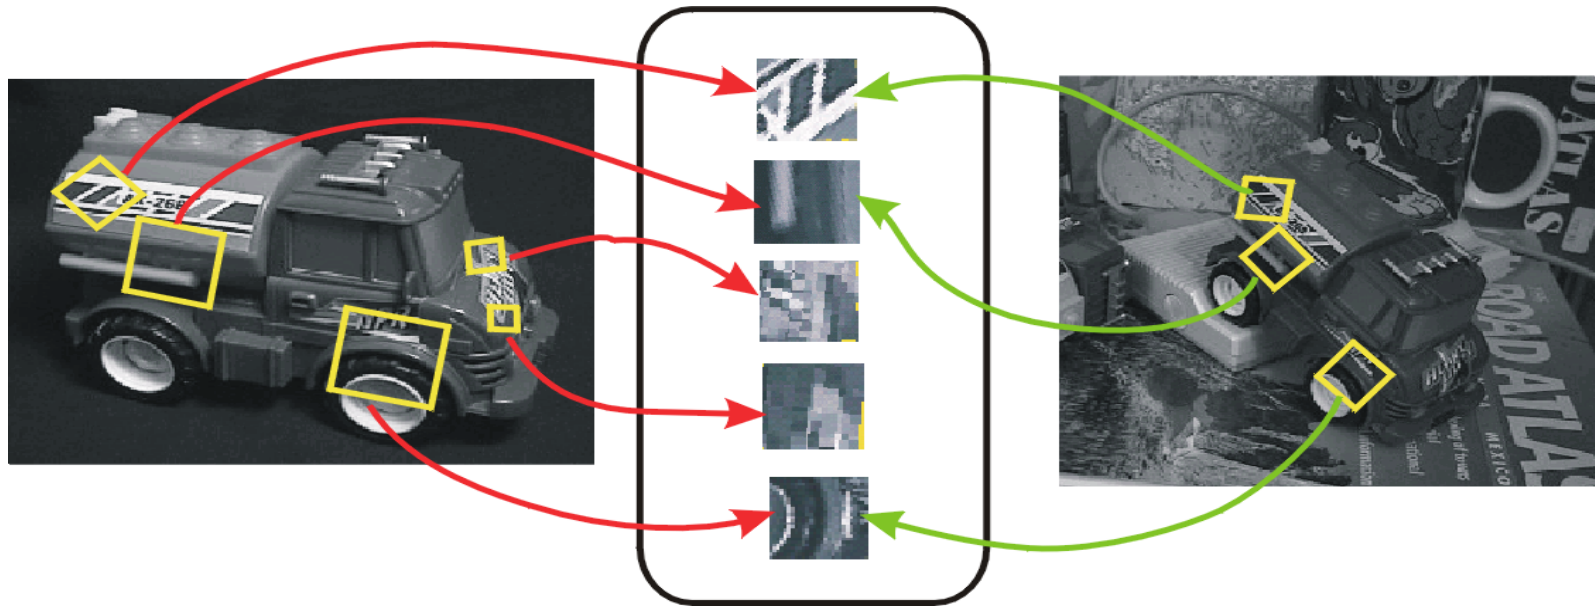

SIFT Reference

Distinctive image features from scale-invariant keypoints. David G. Lowe, *International Journal of Computer Vision*, 60, 2 (2004), pp. 91-110.

SIFT = Scale Invariant Feature Transform

Invariant Local Features

- Image content is transformed into local feature coordinates that are invariant to translation, rotation, scale, and other imaging parameters

SIFT Features

Advantages of invariant local features

- **Locality:** features are local, so robust to occlusion and clutter (no prior segmentation)
- **Distinctiveness:** individual features can be matched to a large database of objects
- **Quantity:** many features can be generated for even small objects
- **Efficiency:** close to real-time performance
- **Extensibility:** can easily be extended to wide range of differing feature types, with each adding robustness

SIFT On-A-Slide

1. **Enforce invariance to scale:** Compute Gaussian difference max, for many different scales; non-maximum suppression, find local maxima: keypoint candidates
2. **Localizable corner:** For each maximum fit quadratic function. Compute center with sub-pixel accuracy by setting first derivative to zero.
3. **Eliminate edges:** Compute ratio of eigenvalues, drop keypoints for which this ratio is larger than a threshold.
4. **Enforce invariance to orientation:** Compute orientation, to achieve rotation invariance, by finding the strongest second derivative direction in the smoothed image (possibly multiple orientations). Rotate patch so that orientation points up.
5. **Compute feature signature:** Compute a "gradient histogram" of the local image region in a 4x4 pixel region. Do this for 4x4 regions of that size. Orient so that largest gradient points up (possibly multiple solutions). Result: feature vector with 128 values (15 fields, 8 gradients).
6. **Enforce invariance to illumination change and camera saturation:** Normalize to unit length to increase invariance to illumination. Then threshold all gradients, to become invariant to camera saturation.

SIFT On-A-Slide

1. **Enforce invariance to scale:** Compute Gaussian difference max, for many different scales; non-maximum suppression, find local maxima: keypoint candidates
2. **Localizable corner:** For each maximum fit quadratic function. Compute center with sub-pixel accuracy by setting first derivative to zero.
3. **Eliminate edges:** Compute ratio of eigenvalues, drop keypoints for which this ratio is larger than a threshold.
4. **Enforce invariance to orientation:** Compute orientation, to achieve rotation invariance, by finding the strongest second derivative direction in the smoothed image (possibly multiple orientations). Rotate patch so that orientation points up.
5. **Compute feature signature:** Compute a "gradient histogram" of the local image region in a 4x4 pixel region. Do this for 4x4 regions of that size. Orient so that largest gradient points up (possibly multiple solutions). Result: feature vector with 128 values (15 fields, 8 gradients).
6. **Enforce invariance to illumination change and camera saturation:** Normalize to unit length to increase invariance to illumination. Then threshold all gradients, to become invariant to camera saturation.

Select canonical orientation

- Create histogram of local gradient directions computed at selected scale
- Assign canonical orientation at peak of smoothed histogram
- Each key specifies stable 2D coordinates (x , y , scale, orientation)

SIFT On-A-Slide

1. **Enforce invariance to scale:** Compute Gaussian difference max, for many different scales; non-maximum suppression, find local maxima: keypoint candidates
2. **Localizable corner:** For each maximum fit quadratic function. Compute center with sub-pixel accuracy by setting first derivative to zero.
3. **Eliminate edges:** Compute ratio of eigenvalues, drop keypoints for which this ratio is larger than a threshold.
4. **Enforce invariance to orientation:** Compute orientation, to achieve rotation invariance, by finding the strongest second derivative direction in the smoothed image (possibly multiple orientations). Rotate patch so that orientation points up.
5. **Compute feature signature:** Compute a "gradient histogram" of the local image region in a 4x4 pixel region. Do this for 4x4 regions of that size. Orient so that largest gradient points up (possibly multiple solutions). Result: feature vector with 128 values (15 fields, 8 gradients).
6. **Enforce invariance to illumination change and camera saturation:** Normalize to unit length to increase invariance to illumination. Then threshold all gradients, to become invariant to camera saturation.

SIFT vector formation

- Thresholded image gradients are sampled over 16x16 array of locations in scale space
- Create array of orientation histograms
- 8 orientations x 4x4 histogram array = 128 dimensions

Nearest-neighbor matching to feature database

- Hypotheses are generated by **approximate nearest neighbor** matching of each feature to vectors in the database
 - SIFT use best-bin-first (Beis & Lowe, 97) modification to k-d tree algorithm
 - Use heap data structure to identify bins in order by their distance from query point
- **Result:** Can give speedup by factor of 1000 while finding nearest neighbor (of interest) 95% of the time

3D Object Recognition

- Extract outlines with background subtraction

3D Object Recognition

- Only 3 keys are needed for recognition, so extra keys provide robustness
- Affine model is no longer as accurate

Recognition under occlusion

Test of illumination invariance

- Same image under differing illumination

273 keys verified in final match

Vedaldi: This is a test.

Vedaldi: Thanks for noticing the

Done

SIFT

An open implementation of SIFT

This is a MATLAB/C implementation of SIFT detector and descriptor. It is fairly customizable and features a decomposition of the algorithm in several reusable M and MEX files. This implementation produces interest points and descriptors which are very similar to [David Lowe's implementation](#).

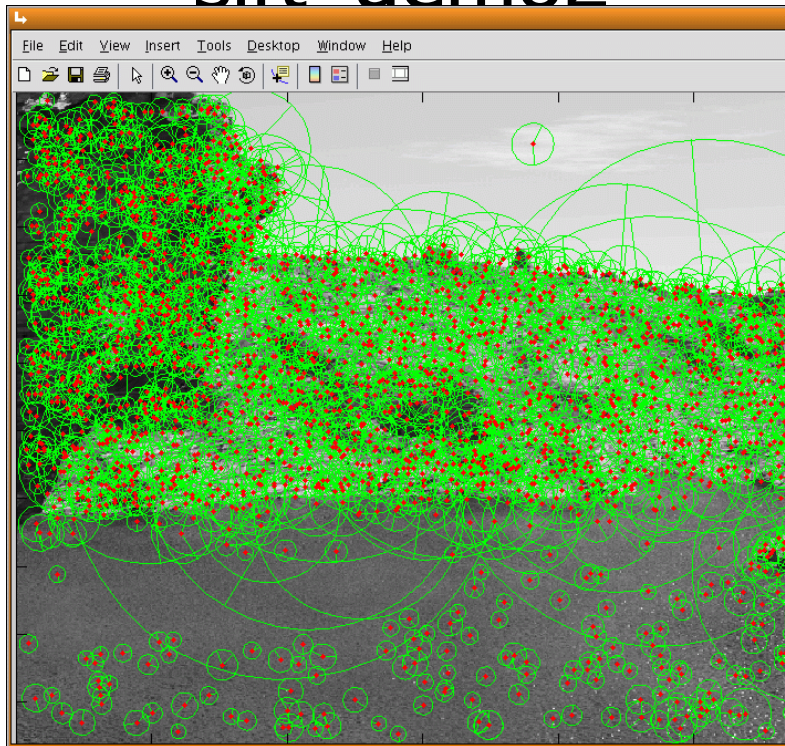

Remark. This code is well suited to study, understand and modify SIFT, but it is not particularly fast. If you need to compute lots of features, you might be interested in [this](#) lightweight C++ version, which does not require MATLAB and comes with a flexible command line interface.

SIFT demos

Run

sift_compile

sift_demo2

Why extract features?

- Motivation: panorama stitching
 - We have two images – how do we combine them?

Step 1: extract features

Step 2: match features

Recognition under occlusion

Test of illumination invariance

- Same image under differing illumination

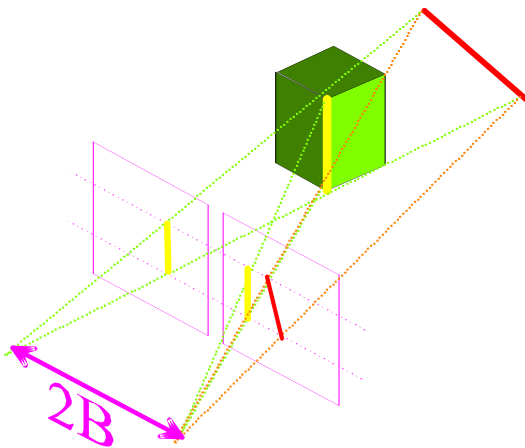

273 keys verified in final match

Stereo Feature Based Reconstruction

Correspondence Problem:

- How to find corresponding areas of two camera images (points, line segments, curves, regions)

- In feature-based matching, the idea is to pick a feature type (e.g. edges), define a matching criteria (e.g. orientation and contrast sign), and then look for matches within a disparity range
- Feature Matching later

Results - Reconstruction

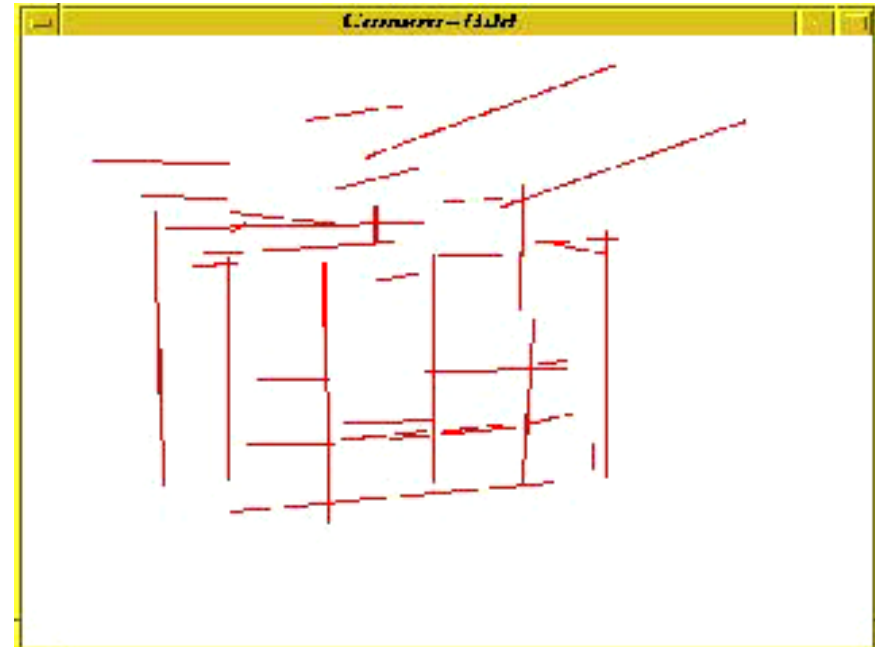

Image Primitives and Correspondence

Given an image point in left image, what is the **(corresponding)** point in the right image, which is the projection of the same 3-D point

Image Primitives and Correspondence

Difficulties – ambiguities, large changes of appearance, due to change
Of viewpoint, non-uniqueness

Matching - Correspondence

Lambertian assumption

$$I_1(\mathbf{x}_1) = \mathcal{R}(p) = I_2(\mathbf{x}_2)$$

Rigid body motion

$$\mathbf{x}_2 = h(\mathbf{x}_1) = \frac{1}{\lambda_2(\mathbf{X})} (R\lambda_1(\mathbf{X})\mathbf{x}_1 + T)$$

Correspondence

$$I_1(\mathbf{x}_1) = I_2(h(\mathbf{x}_1))$$

Local Deformation Models

- Translational model

$$h(\mathbf{x}) = \mathbf{x} + d$$

$$I_1(\mathbf{x}_1) = I_2(h(\mathbf{x}_1))$$

- Affine model

$$h(\mathbf{x}) = A\mathbf{x} + d$$

$$I_1(\mathbf{x}_1) = I_2(h(\mathbf{x}_1))$$

- Transformation of the intensity values taking into account occlusions and noise

$$I_1(\mathbf{x}_1) = f_o(\mathbf{X}, g)I_2(h(\mathbf{x}_1) + n(h(\mathbf{x}_1)))$$

Feature Tracking and Optical Flow

- Translational model

$$I_1(\mathbf{x}_1) = I_2(\mathbf{x}_1 + \Delta \mathbf{x})$$

- Small baseline

$$I(\mathbf{x}(t), t) = I(\mathbf{x}(t) + \mathbf{u}dt, t + dt)$$

- RHS approximation by the first two terms of Taylor series

$$\nabla I(\mathbf{x}(t), t)^T \mathbf{u} + I_t(\mathbf{x}(t), t) = 0$$

- Brightness constancy constraint

Aperture Problem

- Normal flow

$$\mathbf{u}_n \doteq \frac{\nabla I^T \mathbf{u}}{\|\nabla I\|} \cdot \frac{\nabla I}{\|\nabla I\|} = -\frac{I_t}{\|\nabla I\|} \cdot \frac{\nabla I}{\|\nabla I\|}$$

Given brightness constancy constraint at single point –
all we can recover is normal flow

Optical Flow

- Integrate around over image patch

$$E_b(\mathbf{u}) = \sum_{W(x,y)} [\nabla I^T(x, y, t) \mathbf{u}(x, y) + I_t(x, y, t)]^2$$

- Solve
$$\begin{aligned} \nabla E_b(\mathbf{u}) &= 2 \sum_{W(x,y)} \nabla I (\nabla I^T \mathbf{u} + I_t) \\ &= 2 \sum_{W(x,y)} \left(\begin{bmatrix} I_x^2 & I_x I_y \\ I_x I_y & I_y^2 \end{bmatrix} \mathbf{u} + \begin{bmatrix} I_x I_t \\ I_y I_t \end{bmatrix} \right) \end{aligned}$$

$$\begin{bmatrix} \sum I_x^2 & \sum I_x I_y \\ \sum I_x I_y & \sum I_y^2 \end{bmatrix} \mathbf{u} + \begin{bmatrix} \sum I_x I_t \\ \sum I_y I_t \end{bmatrix} = 0$$
$$G\mathbf{u} + \mathbf{b} = 0$$

Optical Flow, Feature Tracking

$$\mathbf{u} = -G^{-1}\mathbf{b}$$

$$G = \begin{bmatrix} \sum I_x^2 & \sum I_x I_y \\ \sum I_x I_y & \sum I_y^2 \end{bmatrix}$$

Conceptually:

rank(G) = 0 blank wall problem

rank(G) = 1 aperture problem

rank(G) = 2 enough texture – good feature candidates

In reality: choice of threshold is involved

Optical Flow

- Previous method - assumption locally constant flow

- Alternative regularization techniques (locally smooth flow fields, integration along contours)
- Qualitative properties of the motion fields

Point Feature Extraction

$$G = \begin{bmatrix} \sum I_x^2 & \sum I_x I_y \\ \sum I_x I_y & \sum I_y^2 \end{bmatrix}$$

- Compute eigenvalues of G
- If smallest eigenvalue σ of G is bigger than τ - mark pixel as candidate feature point

- Alternatively feature quality function (Harris Corner Detector)

$$C(G) = \det(G) + k \cdot \text{trace}^2(G)$$

Harris Corner Detector - Example

Feature Selection

- Compute Image Gradient $\nabla I^T = [I_x, I_y]$
- Compute Feature Quality measure for each pixel

$$C(\mathbf{x}) = \det(G) + k \cdot \text{trace}^2(G) \quad G = \begin{bmatrix} \sum I_x^2 & \sum I_x I_y \\ \sum I_x I_y & \sum I_y^2 \end{bmatrix}$$

- Search for local maxima

Feature Quality Function

Local maxima of feature quality function

Feature Tracking

- Translational motion model

$$E(\mathbf{d}) = \min_{\mathbf{d}} \sum_{W(\mathbf{x})} [I_2(\tilde{\mathbf{x}} + \mathbf{d}) - I_1(\tilde{\mathbf{x}})]^2$$

- Closed form solution

$$\mathbf{d} = -G^{-1} \mathbf{b}$$

$$G = \begin{bmatrix} \sum I_x^2 & \sum I_x I_y \\ \sum I_x I_y & \sum I_y^2 \end{bmatrix}$$

$$\mathbf{b} \doteq \begin{bmatrix} \sum_{W(\mathbf{x})} I_x I_t \\ \sum_{W(\mathbf{x})} I_y I_t \end{bmatrix}$$

- Build an image pyramid
- Start from coarsest level
- Estimate the displacement at the coarsest level
- Iterate until finest level

Coarse to fine feature tracking

2

1

0

1. compute $\mathbf{d}_k = -G\mathbf{b}$
2. warp the window $W(\mathbf{x})$ in the second image by
3. update the displacement $\mathbf{d} \leftarrow \mathbf{d} + 2\mathbf{d}_k$
4. go to finer level $k \leftarrow k - 1$
5. At the finest level repeat for several iterations

Let's watch the result:

(Stanley before turning blue.)

Color Vision

- With the advent of inexpensive color imagery and processing, color information can be used effectively for machine vision.
- Color provides multiple information per pixel, often enabling complex classification.
- Perception of Color depends on three factors:
 - The spectrum of energy in various wavelengths illuminating the object surface,
 - The spectral reflectance of the object surface, which determines how the surface changes the received spectrum into the radiated spectrum,
 - The spectral sensitivity of the sensor irradiated by the object's surface.

Blue

Application

- Color Consider the problem of locating/segmenting faces from images using color.
- First we need to identify the range of colors that could be associated with a face.
- The lighting conditions would play a significant role.
- Even under uniform illumination, other objects could fall into that color space. In this case we could use shape information for the purpose of segmentation.

Color space analysis

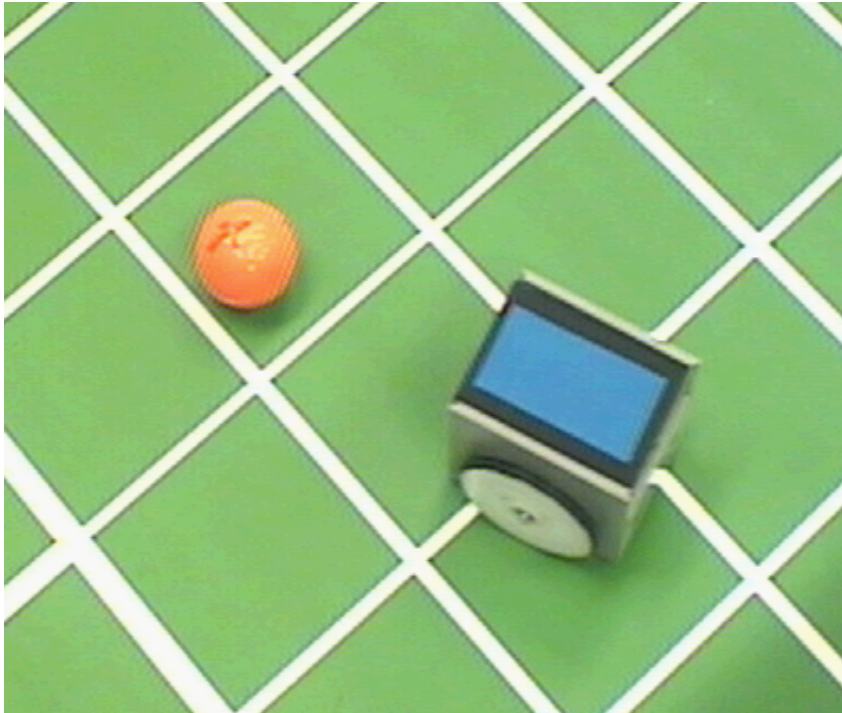

T4 – primary face color, t-5 and t-6 secondary face clusters

-
- Three major steps are involved in the face segmentation procedure
 - First we need to create a labeled image based on the training data for identifying the color space that would represent the face.
 - Connected component is used to merge regions that would be part of the face.
 - The face is identified as the largest component and areas close to the components are merged.

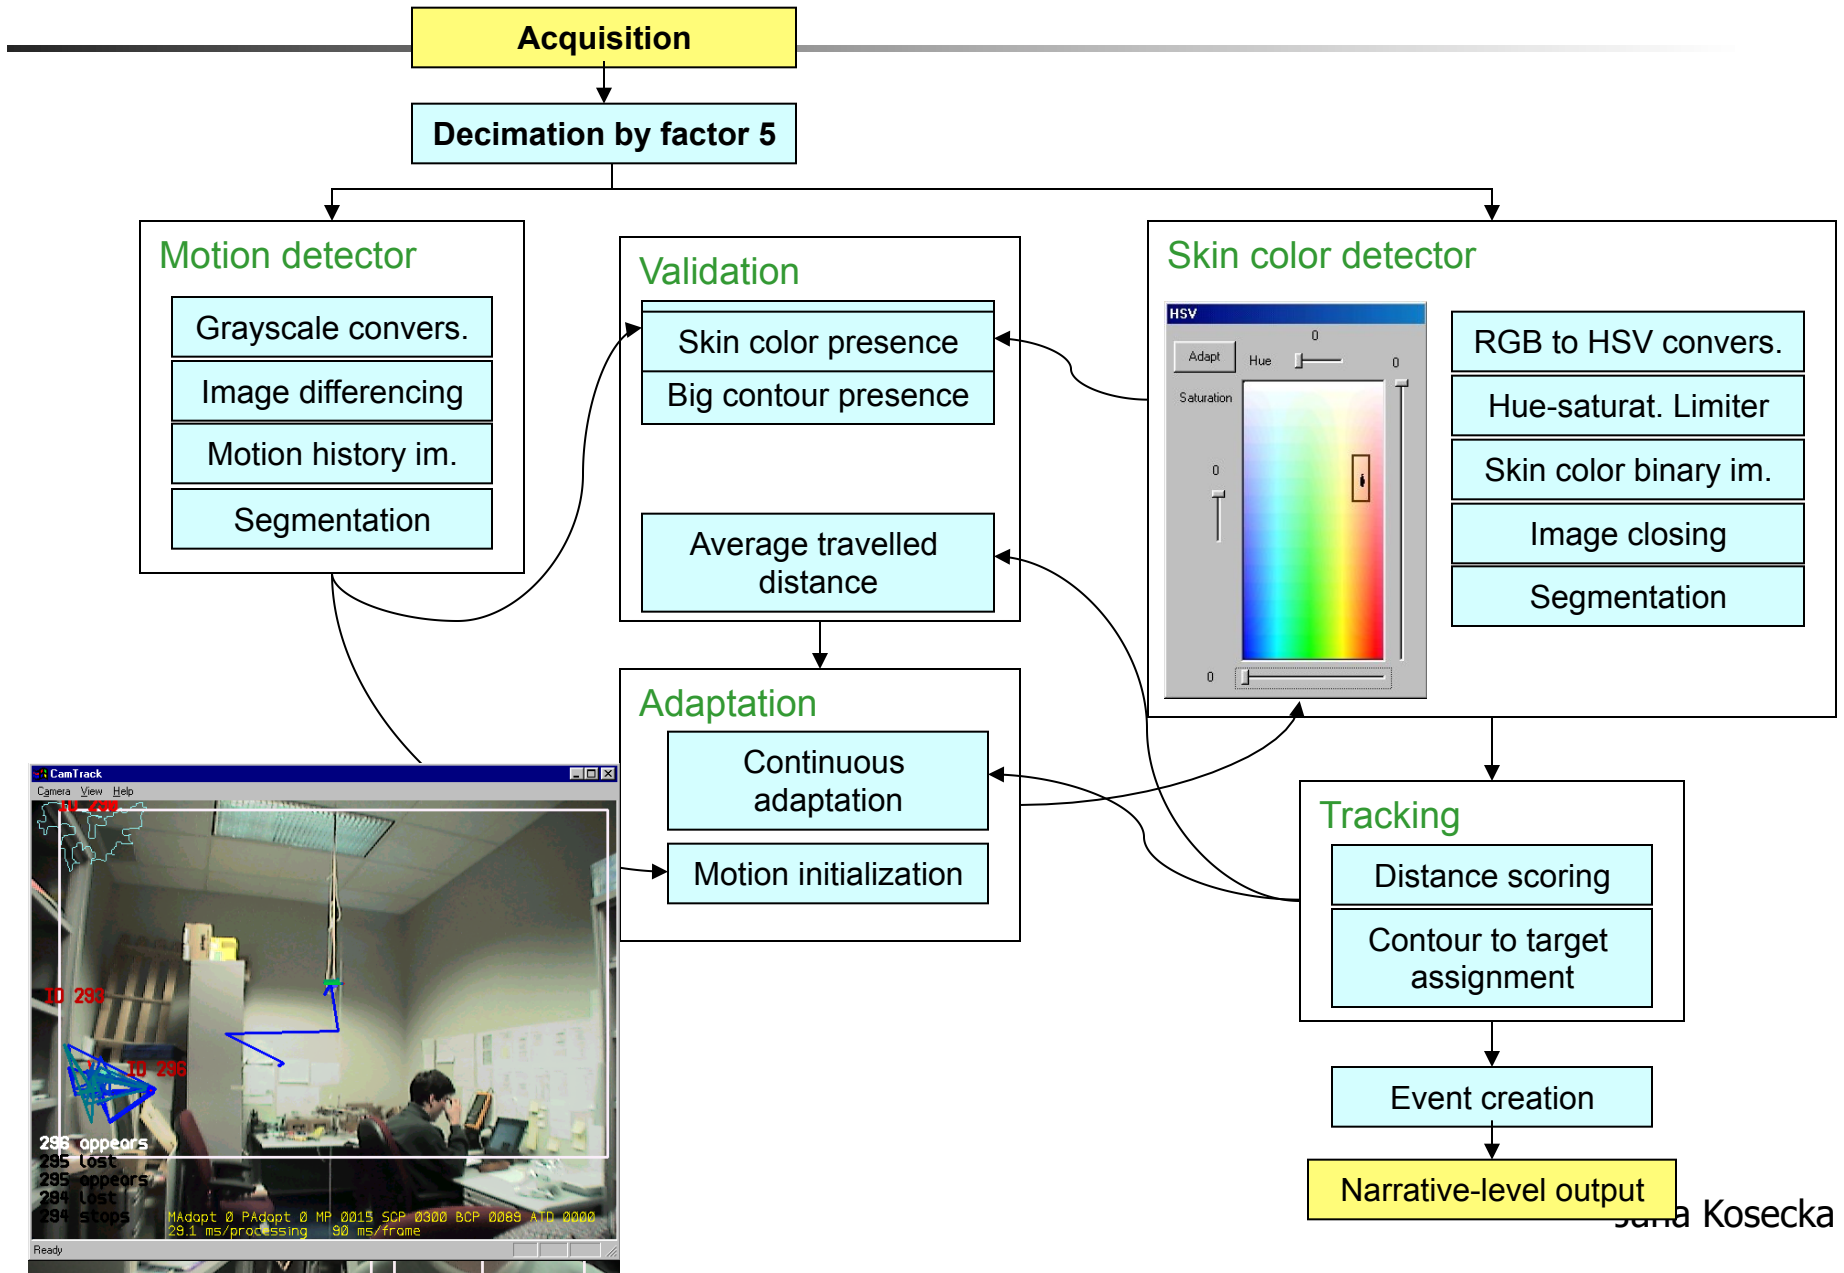

Color Tracking Sensors

- Motion estimation of ball and robot for soccer playing using color tracking
