CS483 Analysis of Algorithms Lecture 11 – NP-completeness *

Jyh-Ming Lien

April 23, 2009

^{*}this lecture note is based on *Algorithms* by S. Dasgupta, C.H. Papadimitriou, and U.V. Vazirani and *Introduction to the Design and Analysis of Algorithms* by Anany Levitin.

Hard Problems

Hard Problems

Search Problems

Complexity Class

Reductions

□ Search problems (formal definition later):

- Search for shortest path in a graph

...

- Search for values of x, y and z to satisfy: $x^2y^{\frac{1}{2}}z xz^2 = 7$
- Search for a path in 3D space among obstacles

□ Success on solving these hard problems in polynomial time

- **Greedy** properties: without looking backward or forward, MST, shortest paths
- Optimality from subproblems: divide and conquer, dynamic programming
- **Convexity**: gradient decent/hill climbing, linear programming
- □ Success on solving these hard problems is based on some **special properties** of the problems

Hard Problems

Hard Problems Hard Problems

Search Problems

Complexity Class

Reductions

Failures

- Many problems requires 2^n , n! or even n^n (intractable)
- For some (clearly formalized) problems we don't even have algorithms to solve them
- (not to mention those problems that we can not even formalize)
- $\hfill\square$ In this lecture, we will look at
 - What are these *problems*? (Search Problems)
 - Terminology to classify *problems*: **P vs. NP**
 - How do you know if a *problem* can be solved efficiently?
 (Problem Reduction)
 - Do we have any hope of solving these *problems* efficiently?

What Are Search

Optimization Problems

\Box A Search problem has

- An instance of problem *I* that is input data specifying the problem
- Asked to find a solution S that meets a particular specification
- Polynomial-time Checkable: There most be an algorithm C that takes I and S and checks for correctness *efficiently*, i.e., in polynomial time

□ Example: Satisfability problem

- $I: (x \lor y \lor z)(x \lor \overline{y})$ $- S: \{x = T, y = F, z = T\}$ $- C: (T \lor F \lor T)(T \lor \overline{F})$
- □ Example: Traveling salesman problem

$$- I: G = \{V, E\}$$

$$- S: \{v_i, v_k, \cdots, v_i\}$$

$$- C:$$

Optimization Problems

Search Problems What Are Search Problems? ▷ Optimization Problems Search Problems Search Problems Search Problems Search Problems Search Problems Search Problems

Complexity Class

Reductions

 \Box We convert an optimization problem to a search problem

- by introduce a **budge** b
- Budget does not make the problem harder or easier.

 \Box Example: Traveling salesman problem with budget b

-
$$I: G = \{V, E\}, b$$

- $S: \{v_i, v_k, \cdots, v_i\}$
- $C:$

 \Box Why do we convert an optimization problem to a search problem?

Hard Problems Hard Problems

Search Problems What Are Search Problems? Optimization Problems Search Problems Search Problems

Search Problems

Search Problems

Search Problems

Complexity Class

Reductions

- □ Many problems we studied in the previous chapters are search problems, e.g., all-pairs shortest paths problem, single-source shortest paths problem, minimum spanning tree, maximum flow minimum cut, matching, ...
 - But why are these problem tractable? These problems seem to have Very Large search spaces
 - Many algorithms seem to defeat the curse of expoentiality!
- \Box Now, after we have seen the most brilliant successes, it's about time for us to face some failure in this quest.
 - Satisfability (SAT, 2SAT, 3SAT)
 - MST and TSP (traveling salesman problem) with or without budget b
 - Euler and Rudrata
 - Minimum cuts and balanced cuts
 - Integer linear programming or ILP ($Ax \le b$) and Zero-one Equations or ZOE (Ax = 1)
 - Three dimensional matching
 - Independent set, vertex cover, clique problem (with budget *b*)
 - Longest path

Satisfability problems (Horn-SAT, 2SAT, 3SAT, KSAT) Horn's formula \square

- Implications: $(z \land w) \Rightarrow u$
- Pure negative clauses: $(\bar{u} \lor \bar{v} \lor \bar{y})$
- Horn-SAT: Solvable using greedy algorithm

2SAT \square

- in conjunctive normal form (CNF)
- Each clause has two literals
- example: $(x \lor y) \land (\bar{x} \lor z) \land (x \lor \bar{w})$
- Can be solve in polynomail time
- 3SAT \square
 - in conjunctive normal form (CNF)
 - Each clause has 3 literals
 - example: $(x \lor y \lor w) \land (\bar{x} \lor z \lor \bar{y}) \land (x \lor u \lor \bar{w})$
 - No polynomial time algorithm

Search Problems What Are Search Problems? Optimization Problems Search Problems Search Problems Search Problems Search Problems Search Problems Search Problems

Com	plexity	Class

Reductions

- □ Longest path (Taxicab rip-off problem)
 - Give a graph and two nodes s and t, find a path with length at least b from s to t without repeating vertices.
 - no polynomial time algorithm
 - Minimum cuts and balanced cuts
 - Find cuts that split the graph into two sets S and T
 - Minimum cuts problem can be solved using linear programming
 - Balanced cuts: $|S| \ge n/3 |T| \ge n/3$ and there are at most *b* edges between *S* and *T*
 - Balanced cuts problem has no polynomial time algorithm

Reductions

Knapsack problem and Subset sum

- In subset sum, each item has same value and weight
- Both problems have no polynomial time algorithms

Integer linear programming or ILP ($Ax \le b$) and Zero-one Equations or ZOE (Ax = 1)

- Simplex method is not polynomial but LP can be solved in polynomial time
- ILP requires the values of all variables to be integer
- ZOE is a special type of ILP where all values in A are 0 or 1
- Both problems have no polynomial time algorithms

Reductions

Tractable: a problem is tractable if there is an algorithm can solve the problem deterministically in *polynomial time*

Is a problem tractable or intractable?

- yes (given an algorithm to support this answer)

– no

- because it's been proved that no algorithm exists at all (e.g., Turing's Halting Problem.)
- because it's been be proved that any algorithm takes exponential time (Traveling Sales Men Problem)

– we have no idea...

If we reduce a problem A to a problem B in polynomial time (denoted as $A \rightarrow B$, we can say that B is as hard as A if not harder

- If $A \to B$ and A is NP-complete then we know that B is also NP-complete
