Communication in Distributed Systems: RPC/RMI

Motivation

- Sockets API \(\equiv\) send & recv calls \(\equiv\) I/O
- Remote Procedure Calls (RPC)
  - Goal: to provide a procedural interface for distributed (i.e., remote) services
  - To make distributed nature of service transparent to the programmer
    - No longer considered a good thing
- Remote Method Invocation (RMI)
  - RPC + Object Orientation
  - Allows objects living in one process to invoke methods of an object living in another process
Middleware layers

- Applications, services
- RMI and RPC
- Request-reply protocol
  - marshalling and external data representation
- UDP and TCP

Conventional Procedure Call

a) Parameter passing in a local procedure call: the stack before the call to `read(fd,buf,bytes)`

b) The stack while the called procedure is active

![Diagram of stack for conventional procedure call](image)
Remote Procedure Call

- Principle of RPC between a client and server program.

![Diagram of RPC between client and server](Image)

Remote Procedure Calls

- Remote procedure call (RPC) abstracts procedure calls between processes on networked systems.
- **Stubs** - client-side proxy for the actual procedure on the server.
- The **client-side stub** locates the server and marshals the parameters.
- The **server-side stub** receives this message, unpacks the marshalled parameters, and performs the procedure on the server.
**Steps of a Remote Procedure Call**

1. Client procedure calls client stub in normal way
2. Client stub builds message, calls local OS
3. Client’s OS sends message to remote OS
4. Remote OS gives message to server stub
5. Server stub unpacks parameters, calls server
6. Server does work, returns result to the stub
7. Server stub packs it in message, calls local OS
8. Server’s OS sends message to client’s OS
9. Client’s OS gives message to client stub
10. Stub unpacks result, returns to client

**Passing Value Parameters (1)**

[Diagram showing the steps of a remote procedure call and passing value parameters.]
Passing Value Parameters (2)

(a) Original message on the Pentium
(b) The message after receipt on the SPARC
(c) The message after being inverted. The little numbers in boxes indicate the address of each byte

Parameter Specification and Stub Generation

(a) A procedure
(b) The corresponding message.

foobar( char x; float y; int z[5] )
{
    ....
}

<table>
<thead>
<tr>
<th>foobar's local variables</th>
</tr>
</thead>
<tbody>
<tr>
<td>x</td>
</tr>
<tr>
<td>y</td>
</tr>
<tr>
<td>5</td>
</tr>
<tr>
<td>z[0]</td>
</tr>
<tr>
<td>z[1]</td>
</tr>
<tr>
<td>z[2]</td>
</tr>
<tr>
<td>z[3]</td>
</tr>
<tr>
<td>z[4]</td>
</tr>
</tbody>
</table>

Request-reply communication

Writing a Client and a Server

The steps in writing a client and a server in DCE RPC (SUN RPC is similar)
Files interface in Sun XDR

```
const MAX = 1000;
typedef int FileIdentifier;
typedef int FilePointer;
typedef int Length;
struct Data {
    int length;
    char buffer[MAX];
};
struct writeargs {
    FileIdentifier f;
    FilePointer position;
    Data data;
};
struct readargs {
    FileIdentifier f;
    FilePointer position;
    Length length;
};

program FILEREADWRITE {
    version VERSION {
        void WRITE(writeargs)=1;
        Data READ(readargs)=2;
    }=2;
} = 9999;
```

See additional slides on client and server programs

---

Binding a Client to a Server

NOTE: In SunRPC, you only have to register the service (not both service and endpoint). Each host runs its own binder process called portmapper
RMI

- RMI = RPC + Object-orientation
  - Java RMI
  - CORBA
    - Middleware that is language-independent
  - Microsoft DCOM/COM+
  - SOAP
    - RMI on top of HTTP

Interfaces in distributed systems

- Programs organized as a set of modules that communicate with one another via procedure calls/method invocations
- Explicit interfaces defined for each module in order to control interactions between modules
- In distributed systems, modules can be in different processes
- A remote interface specifies the methods of an object that are available for invocation by objects in other processes defining the types of the input and output arguments of each of them
Remote and local method invocations

A remote object and its remote interface
The role of proxy and skeleton in remote method invocation

Request-reply communication for RPC/RMI
**Operations of the request-reply protocol**

`public byte[] doOperation (RemoteObjectRef o, int methodId, byte[] arguments)`

sends a request message to the remote object and returns the reply.

The arguments specify the remote object, the method to be invoked and the arguments of that method.

`public byte[] getRequest ()`;

acquires a client request via the server port.

`public void sendReply (byte[] reply, InetAddress clientHost, int clientPort)`;

sends the reply message reply to the client at its Internet address and port.

---

**Request-reply message structure**

<table>
<thead>
<tr>
<th>messageType</th>
<th>int (0=Request, 1=Reply)</th>
</tr>
</thead>
<tbody>
<tr>
<td>requestId</td>
<td>int</td>
</tr>
<tr>
<td>objectReference</td>
<td>RemoteObjectRef</td>
</tr>
<tr>
<td>methodId</td>
<td>int or Method</td>
</tr>
<tr>
<td>arguments</td>
<td>array of bytes</td>
</tr>
</tbody>
</table>
Request-Reply protocol

- Issues in **marshalling** of parameters and results
  - Input, output, Inout parameters
  - Data representation
  - Passing pointers? (e.g., call by reference in C)
- Distributed object references
- Handling failures in request-reply protocol
  - Partial failure
    - Client, Server, Network

CORBA CDR message

<table>
<thead>
<tr>
<th>index in sequence of bytes</th>
<th>4 bytes</th>
<th>notes on representation</th>
</tr>
</thead>
<tbody>
<tr>
<td>0-3</td>
<td>5</td>
<td>length of string</td>
</tr>
<tr>
<td>4-7</td>
<td>&quot;Smith&quot;</td>
<td>‘Smith’</td>
</tr>
<tr>
<td>8-11</td>
<td>&quot;h___&quot;</td>
<td></td>
</tr>
<tr>
<td>12-15</td>
<td>6</td>
<td>length of string</td>
</tr>
<tr>
<td>16-19</td>
<td>&quot;London&quot;</td>
<td>‘London’</td>
</tr>
<tr>
<td>20-23</td>
<td>&quot;on__&quot;</td>
<td></td>
</tr>
<tr>
<td>24-27</td>
<td>1934</td>
<td>unsigned long</td>
</tr>
</tbody>
</table>

The flattened form represents a `Person` struct with value: `{‘Smith’, ‘London’, 1934}`
**Java serialization**

<table>
<thead>
<tr>
<th>Person</th>
<th>8-byte version number</th>
<th>Explanation</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>int year</td>
<td>class name, version number</td>
</tr>
<tr>
<td></td>
<td>java.lang.String</td>
<td>number, type and name of instance variables</td>
</tr>
<tr>
<td>1934</td>
<td>5 Smith 6 London</td>
<td>values of instance variables</td>
</tr>
</tbody>
</table>

The true serialized form contains additional type markers; h0 and h1 are handles.

---

**RMI Programming**

- **RMI software**
  - **Generated by IDL compiler**
  - **Proxy**
    - Behaves like remote object to clients (invoker)
    - Marshals arguments, forwards message to remote object, unmarshals results, returns results to client
  - **Skeleton**
    - Server side stub;
    - Unmarshals arguments, invokes method, marshals results and sends to sending proxy's method
  - **Dispatcher**
    - Receives the request message from communication module, passes on the message to the appropriate method in the skeleton

- **Server and Client programs**
**RMI Programming**

- **Binder**
  - Client programs need a means of obtaining a remote object reference
  - Binder is a service that maintains a mapping from textual names to remote object references
  - Servers need to register the services they are exporting with the binder
  - Java RMIRegistry, CORBA Naming service

- **Server threads**
  - Several choices: thread per object, thread per invocation
  - Remote method invocations must allow for concurrent execution

**RPC/RMI systems**

- **RPC systems**
  - SUN RPC
  - DCE RPC

- **RMI systems**
  - CORBA
  - DCOM
  - Java RMI
  - SOAP (Simple Object Access Protocol)
    - HTTP is request-reply protocol
    - XML for data representation
Java RMI

Features
- Integrated with Java language + libraries
  - Security, write once run anywhere, multithreaded
  - Object orientation
- Can pass “behavior”
  - Mobile code
  - Not possible in CORBA, traditional RPC systems
- Distributed Garbage Collection
- Remoteness of objects intentionally not transparent

Remote Interfaces, Objects, and Methods

- Objects become remote by implementing a remote interface
  - A remote interface extends the interface java.rmi.Remote
  - Each method of the interface declares java.rmi.RemoteException in its throws clause in addition to any application-specific clauses
Creating distributed applications using RMI

1. Define the remote interfaces
2. Implement the remote objects
3. Implement the client (can be done anytime after remote interfaces have been defined)
4. Register the remote object in the name server registry
5. Generate the stub and client using rmic
6. Start the registry
7. Start the server
8. Run the client

Java Remote interfaces Shape and ShapeList

```java
import java.rmi.*;
import java.util.Vector;
public interface Shape extends Remote {
    int getVersion() throws RemoteException;
    GraphicalObject getAllState() throws RemoteException;
}
public interface ShapeList extends Remote {
    Shape newShape(GraphicalObject g) throws RemoteException;
    Vector allShapes() throws RemoteException;
    int getVersion() throws RemoteException;
}
```
The Naming class of Java RMIIregistry

**void rebind (String name, Remote obj)**
This method is used by a server to register the identifier of a remote object by name, as shown in Figure 15.13, line 3.

**void bind (String name, Remote obj)**
This method can alternatively be used by a server to register a remote object by name, but if the name is already bound to a remote object reference an exception is thrown.

**void unbind (String name, Remote obj)**
This method removes a binding.

**Remote lookup(String name)**
This method is used by clients to look up a remote object by name, as shown in Figure 15.15  line 1. A remote object reference is returned.

**String [] list()**
This method returns an array of Strings containing the names bound in the registry.

Java class ShapeListServer with main method

```java
import java.rmi.*;
public class ShapeListServer{
    public static void main(String args[]){
        System.setSecurityManager(new RMISecurityManager());
        try{
            ShapeList aShapeList = new ShapeListServant(); 1
            Naming.rebind("Shape List", aShapeList ); 2
            System.out.println("ShapeList server ready");
        }catch(Exception e ) {
            System.out.println("ShapeList server main " + e.getMessage());
        }
    }
}
```

Communication in Dist. Systems 33
Java class `ShapeListServant` implements interface `ShapeList`:

```java
import java.rmi.*;
import java.rmi.server.UnicastRemoteObject;
import java.util.Vector;
public class ShapeListServant extends UnicastRemoteObject implements ShapeList {
    private Vector theList; // contains the list of Shapes
    private int version;
    public ShapeListServant() throws RemoteException {...}
    public Shape newShape(GraphicalObject g) throws RemoteException {
        version++;
        Shape s = new ShapeServant(g, version);
        theList.addElement(s);
        return s;
    }
    public Vector allShapes() throws RemoteException {
    }
    public int getVersion() throws RemoteException {
    }
}
```

Java client of `ShapeList`:

```java
import java.rmi.*;
import java.rmi.server.*;
import java.util.Vector;
public class ShapeListClient{
    public static void main(String args[]) {
        System.setSecurityManager(new RMISecurityManager());
        ShapeList aShapeList = null;
        try{
            aShapeList = (ShapeList) Naming.lookup("//bruno.ShapeList");
            Vector sList = aShapeList.allShapes();
        } catch(RemoteException e) {System.out.println(e.getMessage());}
    }
}
```
