

# Python Programming: An Introduction to Computer Science

## Chapter 2

Dan Fleck

Coming up: The Software  
Development Process

1

## The Software Development Process

- The process of creating a program is often broken down into stages according to the information that is produced in each phase.

Coming up: The Software Development Process

2

## The Software Development Process

- **Analyze the Problem**  
Figure out exactly the problem to be solved. Try to understand it as much as possible.

Coming up: The Software Development Process

3

## The Software Development Process

- **Determine Specifications**  
Describe exactly what your program will do.
  - Don't worry about *how* the program will work, but *what* it will do.
  - Includes describing the inputs, outputs, and how they relate to one another.

Coming up: The Software Development Process

4

# The Software Development Process

- **Create a Design**

- Formulate the overall structure of the program.
- This is where the *how* of the program gets worked out.
- You choose or develop your own algorithm that meets the specifications.

Coming up: The Software Development Process

5

## The Software Development Process

- **Implement the Design**

- Translate the design into a computer language.
- In this course we will use Python.

Coming up: The Software Development Process

6

## The Software Development Process

- **Test/Debug the Program**

- Try out your program to see if it worked.
- If there are any errors (*bugs*), they need to be located and fixed. This process is called *debugging*.
- Your goal is to find errors, so try everything that might “break” your program!

Coming up: Why is it called debugging?

7

## Why is it called debugging?

Photo # NH 96566-KN First Computer "Bug", 1945

## The First "Computer Bug"

Moth found trapped between points at Relay # 70, Panel F, of the Mark II Aiken Relay Calculator while it was being tested at Harvard University, 9 September 1945. The operators affixed the moth to the computer log, with the entry: **"First actual case of bug being found"**. They put out the word that they had **"debugged"** the machine, thus introducing the term 'debugging a computer program'.

Courtesy of the Naval Surface Warfare Center, Dahlgren, VA., 1988. *U.S. Naval Historical Center Photograph.*

Coming up: The Software Development Process

8

## The Software Development Process

- **Maintain the Program**
  - Continue developing the program in response to the needs of your users.
  - In the real world, most programs are never completely finished – they evolve over time.

Coming up: Example : Temperature Converter Analysis

9

## Example : Temperature Converter Analysis

- Analysis – the temperature is given in Celsius, user wants it expressed in degrees Fahrenheit.
- Specification
  - Input – temperature in Celsius
  - Output – temperature in Fahrenheit
  - Output =  $9/5(\text{input}) + 32$

Coming up: Example : Temperature Converter Design

10

## Example : Temperature Converter Design

- Design
  - Input, Process, Output (IPO)
  - Prompt the user for input (Celsius temperature)
  - Process it to convert it to Fahrenheit using  $F = 9/5(C) + 32$
  - Output the result by displaying it on the screen

Coming up: Example : Temperature Converter

11

## Example : Temperature Converter

- Before we start coding, let's write a rough draft of the program in *pseudocode*
- Pseudocode is precise English that describes what a program does, step by step. However, There is no "official" syntax for pseudocode
- Using pseudocode, we can concentrate on the algorithm rather than the programming language.

Coming up: Temperature Converter Pseudocode

12

## Temperature Converter Pseudocode

- Pseudocode:
  - Input the temperature in degrees Celsius (call it celsius)
  - Calculate fahrenheit as  $(9/5)*celsius+32$
  - Output fahrenheit
- Now we need to convert this to Python!

Coming up: Temperature Converter Python Code

13

## Temperature Converter Python Code

```
#convert.py
# A program to convert Celsius temps to Fahrenheit
# by: Susan Computewell

def main():
    celsius = input("What is the Celsius temperature? ")
    fahrenheit = (9.0/5.0) * celsius + 32
    print "The temperature is ",fahrenheit," degrees Fahrenheit."

main()
```

Coming up: Temperature Converter Testing

14

## Temperature Converter Testing

- Once we write a program, we should test it!

```
>>>
What is the Celsius temperature? 0
The temperature is 32.0 degrees Fahrenheit.
>>> main()
What is the Celsius temperature? 100
The temperature is 212.0 degrees Fahrenheit.
>>> main()
What is the Celsius temperature? -40
The temperature is -40.0 degrees Fahrenheit.
>>>
```

Coming up: Elements of Programs : Identifiers

15

## Elements of Programs : Identifiers

- Names of values: celsius, fahrenheit
- Names of functions: range, main, input
- Names of modules: convert

These names are called *identifiers*

- Every identifier must begin with a letter or underscore (" \_"), followed by any sequence of letters, digits, or underscores.
- Good programmers use meaningful names
- Identifiers are case sensitive.

Coming up: Elements of Programs : Identifiers

16

## Elements of Programs : Identifiers

Identifiers are case sensitive.

- In Python, identifiers:
  - myVar
  - MYVAR
  - myvar
- Are all *DIFFERENT* because Python is case-sensitive

Coming up: Reserved Words

17

## Reserved Words

Some identifiers are part of Python itself. These identifiers are known as *reserved words*. This means they are not available for you to use as a name for a variable, etc. in your program.

and	del	for	is	raise
assert	elif	from	lambda	return
break	else	global	not	try
class	except	if	or	while
continue	exec	import	pass	yield
def	finally	in	print	

Table 2.1: Python Reserved Words.

Coming up: Using identifiers in expressions

18

## Using identifiers in expressions

```
>>> x = 5
>>> x
5
>>> print x
5
>>> print spam
```

```
Traceback (most recent call last):
  File "<pyshell#15>", line 1, in -toplevel-
    print spam
NameError: name 'spam' is not defined
>>>
```

- NameError is the error when you try to use a variable without a value assigned to it.

Coming up: Math Operators

19

## Math Operators

- Simpler expressions can be combined using *operators*.
- +, -, \*, /, \*\*, %
- Spaces are irrelevant within an expression.
- The normal mathematical precedence applies.
- $((x1 - x2) / 2 * n) + (spam / k ** 3)$

Precedence is:  
PEMDAS - (), \*\*, \*, /, +, -

```
>>>
>>>
>>> x = 4
>>> y = 2
>>> x + y
6
>>> x - y
2
>>> x * y
8
>>> x / y
2
>>> x ** y
16
>>>
>>> x * 3
12
>>> d = x * 3
>>> d
12
>>>|
```

Coming up: Elements of Programs

20

## Elements of Programs

- Output Statements
  - A print statement can print any number of expressions.
  - Successive print statements will display on separate lines.
  - A bare print will print a blank line.
  - If a print statement ends with a “,”, the cursor is not advanced to the next line.

Coming up: Elements of Programs

21

## Elements of Programs

```
print 3+4
print 3, 4, 3+4
print
print 3, 4,
print 3+ 4
print "The answer is",
      3+4
```

```
>>>
>>>
>>>
>>> print 3 + 4
7
>>> print 3, 4, 3+4
3 4 7
>>> print
>>>
>>> print 3,4 ; print 3+ 4
3 4
7
>>> print 3,4, ; print 3+ 4
3 4 7
>>> print "The answer is", 3+4
The answer is 7
>>> |
```

Coming up: Assignment Statements

22

## Assignment Statements

- `<variable> = <expr>`  
variable is an identifier, expr is an expression
- The expression on the RHS is evaluated to produce a value which is then associated with the variable named on the LHS.
- `x = 3.9 * x * (1-x)`
- `fahrenheit = 9.0/5.0 * celsius + 32`
- `x = 5`

Coming up: Assignment Statements

23

## Assignment Statements

- Variables can be reassigned as many times as you want!

```
>>> myVar = 0
>>> myVar
0
>>> myVar = 7
>>> myVar
7
>>> myVar = myVar + 1
>>> myVar
8
>>>
```

Coming up: Assigning Input

24

## Assigning Input

- Input: gets input from the user and stores it into a variable.
- `<variable> = input(<prompt>)`

```
>>> x = input("Enter a temp in fahrenheit >")
Enter a temp in fahrenheit >30
>>> x
30
>>>
```

Coming up: Assigning Input

25

## Assigning Input

- First the prompt is evaluated
- The program waits for the user to enter a value and press <enter>
- The expression that was entered is evaluated and assigned to the input variable.

```
>>>
>>> def inp():
>>>     yourinput = input("Input something >")
>>>     print yourinput
>>>
>>> inp()
Input something >3 + 8
11
>>>
```

Coming up: Definite Loops

26

## Definite Loops

- A **definite** loop executes a definite number of times, i.e., at the time Python starts the loop it knows exactly how many **iterations** to do.
- `for <var> in <sequence>:`  
    `<body>`
- The beginning and end of the body are indicated by indentation.

Loop Index

Coming up: Definite Loops: Example 1

27

## Definite Loops: Example 1

```
# sample_for_loops_1.py
# Example of single "for" loop operation:
#
# General form: for <var> in <sequence>:
#               <body>
#
def main():
    for i in range(3):
        print i
    print
    for i in range(3):
        print "??"
    print
    x = 3
    for i in range(x):
        print 88
    print
    for i in range(x):
        x = x + 1
        print (x)
    print
    for i in range(x):
        x = 1
        print x
    main()
```

What prints

What prints

What prints

```

Coming up: Definite Loops: Example 2

28

## Definite Loops: Example 2

```

simple_for_loops_2.py - /Users/rheishma/GMU/Classes/CS-112/E...
# simple_for_loops_2.py
# Example of simple "for" loop operation
# General form: for <var> in <sequence>:
#               <body>

def main():
    for i in range(3):
        print i
    for i in range(3):
        print 77
    print
    x = 3
    for i in range(x):
        print 88
    print
    for i in range(x):
        y = 0
        y = y + 1
        print (y)
    print
    for i in range(x):
        x = x + 1
        print x
        print y
    print y

main()

```

What prints

What prints

Coming up: Built-In Function: Range

## Built-In Function: Range

`range([start], stop [,step])`

Hint: things in [] are optional!

This is a versatile function to create lists containing arithmetic progressions. It is most often used in for loops. The arguments must be plain integers. If the step argument is omitted, it defaults to 1. If the start argument is omitted, it defaults to 0. The full form returns a list of plain integers [start, start + step, start + 2 \* step, ...]. If step is positive, the last element is the largest start + i \* step less than stop; if step is negative, the last element is the smallest start + i \* step greater than stop. step must not be zero (or else ValueError is raised). Example:

```

>>> range(10)
[0, 1, 2, 3, 4, 5, 6, 7, 8, 9]
>>> range(1, 11)
[1, 2, 3, 4, 5, 6, 7, 8, 9, 10]
>>> range(0, 30, 5)
[0, 5, 10, 15, 20, 25]
>>> range(0, -10, -1)
[0, -1, -2, -3, -4, -5, -6, -7, -8, -9]

```

Coming up: How to exit a loop early

## How to exit a loop early

- **break** statement - terminates the nearest enclosing loop.

```

>>>
>>> for myVar in range(10):
    print myVar
    if myVar == 3:
        break
0
1
2
3
>>>

```

Lets see another example in breaktest.py

Coming up: How to skip a loop if needed

## How to skip a loop if needed

- *continue* - continues with the next iteration of the loop.

```
def continueEx1():
    for i in range(10):
        if i > 5:
            continue
        print i,
```

>>> 0 1 2 3 4 5

Lets see example in `continueExamples.py`

### Coming up: Else in a for loop

33

## Else in a for loop

Loop statements may have an `else` clause; it is executed when the loop terminates through exhaustion of the list (with `for`) or when the condition becomes false (with `while`), but not when the loop is terminated by a `break` statement. [Python Docs]

Coming up: For loop else example

34

## For loop else example

```
def elseExample2(input):
    for i in range(input):
        if i > 10:
            print 'i was greater than 10 in the loop'
            break
    else:
        print 'i was never greater than 10 in the loop!'
```

```
>>> elseExample2(9)
i was never greater than 10 in the loop
>>> elseExample(12)
i was greater than 10 in the loop
```

Coming up: How to find information yourself

35

## How to find information yourself

- To the Python docs!
  - <http://docs.python.org/>
  - Library Reference
  - Index
  - range

Coming up: Using Python's Modules

36

## Using Python's Modules

- Python has a lot of code available in modules for you to use
- Using modules, you must "import" them.

```

python.py - /Users/dffleck/Documents/gmu
# Example to calculate the pythagorean theorem
a^2 + b^2 = c^2

import math

def pythag():
    a = input("What is a >")
    b = input("What is b >")
    c = math.sqrt(math.pow(a, 2) + math.pow(b, 2))
    return c

# Run the function
temp = pythag()
print "The length of side c is:", temp

>>>
What is a >3
What is b >4
The length of side c is: 5.0
>>>

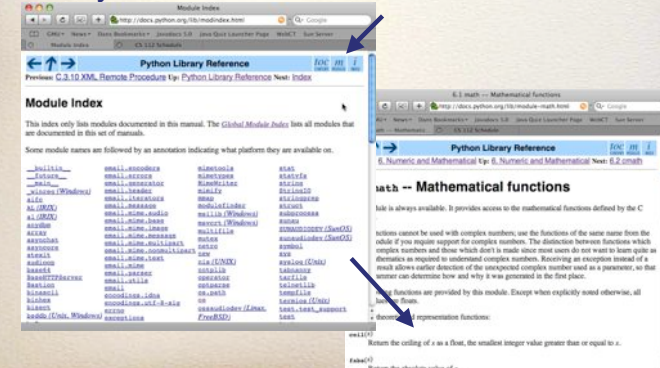

```

Coming up: What modules are available?

37

## What modules are available?

- Many! Find info in the module index

Coming up: Another way to print

38

## Another way to print

```

>>> numCats=5
>>> numDogs=7
>>> print "There were %d cats and %d dogs" %(numCats, numDogs)
There were 5 cats and 7 dogs
>>>
Printing is the SAME. You are formatting the String. This also works:
>>> myString = "There were %d cats and %d dogs" %(numCats,
numDogs)
>>> print myString
There were 5 cats and 7 dogs

```

Inside the String you can put placeholders for other values. The placeholders specify a type.

- %d = Signed integer decimal
- %f = Floating point (decimal format)
- %s = String

Coming up: String formats

39

## String formats

You can also specify a minimum field width like this: "%20d". This will force the number to take up 20 spaces.

```

>>> print "Num 1 = %10f" %(123.456)
Num 1 = 123.456000

```

To print in columns:

```

print "Col1          Col2"
print "%10f          %10f" %(12.23, 222.45)
print "%10f          %10f" %(444.55, 777)

Col1          Col2
12.230000    222.450000
444.550000    777.000000

```

Coming up: Example Program: Future Value

40

### Example Program: Future Value

- Analysis
  - Money deposited in a bank account earns interest.
  - How much will the account be worth 10 years from now?
  - Inputs: principal, interest rate
  - Output: value of the investment in 10 years

Coming up: Example Program: Future Value

41

### Example Program: Future Value

- Specification
  - User enters the initial amount to invest, the principal
  - User enters an annual percentage rate, the interest
  - The specifications can be represent like this ...

Coming up: Example Program: Future Value

42

### Example Program: Future Value

- **Program** Future Value
- **Inputs**
  - principal** The amount of money being invested, in dollars
  - apr** The annual percentage rate expressed as a decimal number.
- **Output** The value of the investment 10 years in the future
- **Relationship** Value after one year is given by  $principal * (1 + apr)$ . This needs to be done 10 times.

Coming up: Example Program: Future Value

43

### Example Program: Future Value

- **Design**
  - Print an introduction
  - Input the amount of the principal (principal)
  - Input the annual percentage rate (apr)
  - Repeat 10 times:
    - $principal = principal * (1 + apr)$
  - Output the value of principal

Coming up: Example Program: Future Value

44

## Example Program: Future Value

- Implementation
  - Each line translates to one line of Python (in this case)
  - Print an introduction  
`print "This program calculates the future"`  
`print "value of a 10-year investment."`
  - Input the amount of the principal  
`principal = input("Enter the initial principal: ")`

Coming up: Example Program: Future Value

45

## Example Program: Future Value

- Input the annual percentage rate  
`apr = input("Enter the annual interest rate: ")`
- Repeat 10 times:  
`for i in range(10):`
- Calculate `principal = principal * (1 + apr)`  
`principal = principal * (1 + apr)`
- Output the value of the principal at the end of 10 years  
`print "The value in 10 years is:", principal`

Coming up: Example Program: Future Value

46

## Example Program: Future Value

```
# futval.py
# A program to compute the value of an investment
# carried 10 years into the future

def main():
    print "This program calculates the future value of a 10-year investment."

    principal = input("Enter the initial principal: ")
    apr = input("Enter the annual interest rate: ")

    for i in range(10):
        principal = principal * (1 + apr)

    print "The value in 10 years is:", principal

main()
```

Coming up: Example Program: Future Value

47

## Example Program: Future Value

```
>>> main()
This program calculates the future value of a 10-year investment.
Enter the initial principal: 100
Enter the annual interest rate: .03
The value in 10 years is: 134.391637934
>>> main()
This program calculates the future value of a 10-year investment.
Enter the initial principal: 100
Enter the annual interest rate: .10
The value in 10 years is: 259.37424601
```

Coming up: Example Program: Future Value

48
