

Python Classes and Objects

The Ball Example

Coming up: Example: Bouncing
Ball

Example: Bouncing Ball

- Lets try to create a bouncing ball class. Essentially this will be a ball that has a velocity and can bounce around a window.
- Specification
 - We want to specify initial position, velocity, color and bounds (where are the walls)
 - We then want to call an update method that moves the ball

Goal

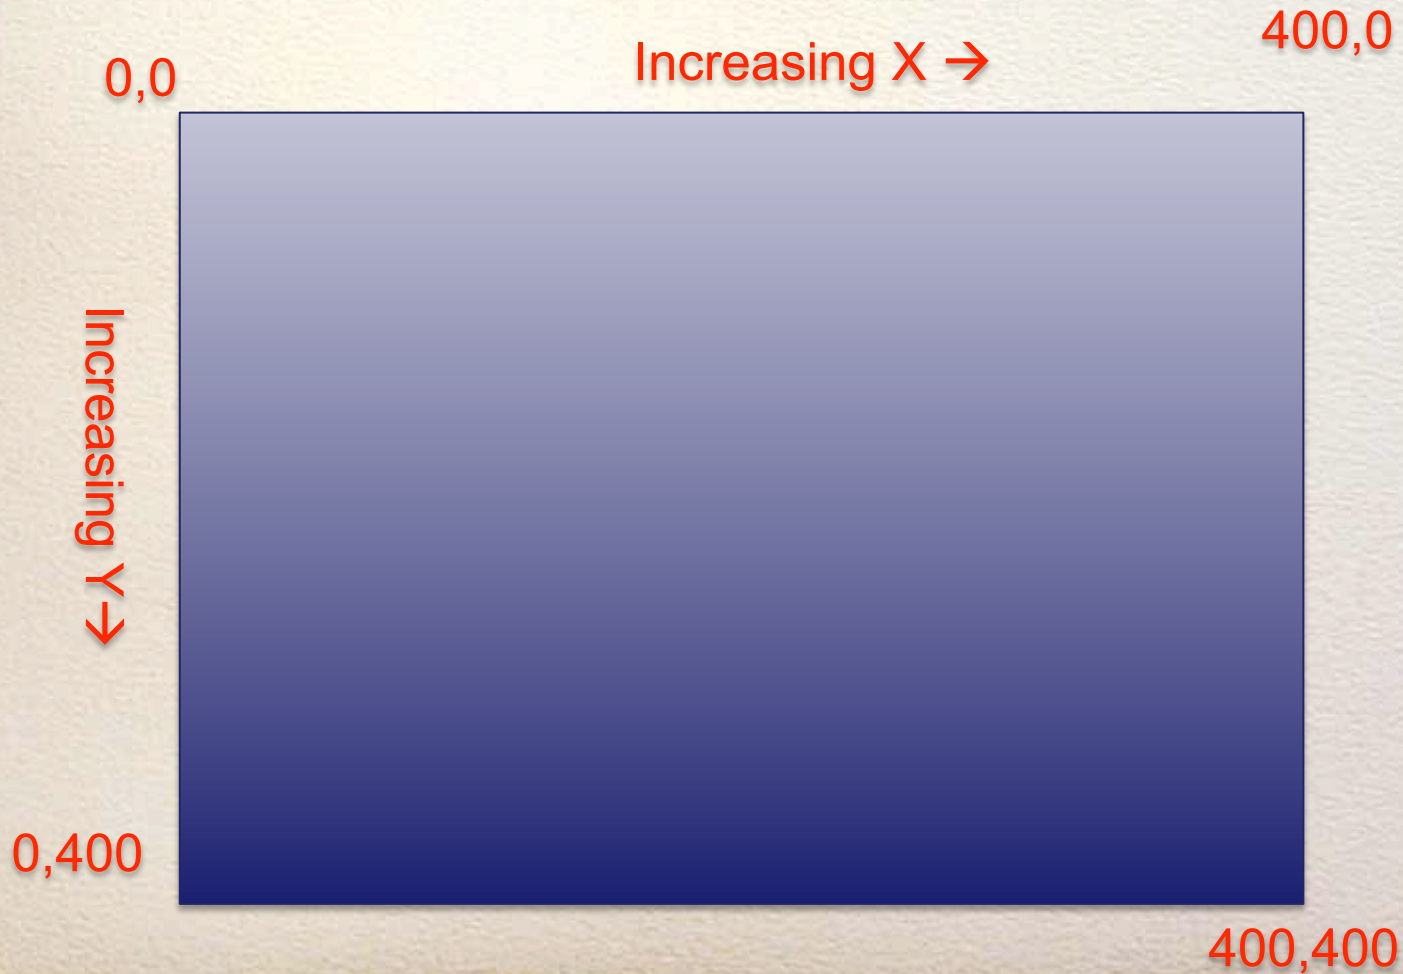

- Create a Ball class that can display a bouncing ball on the screen
- Ball
 - attributes: color, gravity, airResistance, current location, current velocity
 - method:
 - update – sets the location of the ball to a new location based on time incrementing

Creating a Ball

- tkinter is Python's standard graphical toolkit.
- canvas is a class that allows drawing things.
 - # (x1,y1) = upper left corner
 - # (x2,y2) = lower right corner
 - myBall = canvas.create_oval(x1, y1, x2, y2, fill="red")

See [samplecode/objects/ball/DrawCircle.py](#)

Screen Layout

Example: Bouncing Ball

- class Ball:

```
def __init__(self, xLoc, yLoc, xVel, yVel,  
             color, leftWall, rightWall, topWall,  
             bottomWall)
```

```
# Should initialize everything
```

```
def update()
```

```
# Should move the ball and let it bounce  
appropriately
```

Moving something

- Every X seconds, change the location
- From: <http://effbot.org/tkinterbook/canvas.htm>
 - `move(item, dx, dy)` #Moves matching items by an offset.
- `myCanvas.move(myBall,5,0)` # right 5 pixels
- # Call a function or method after 5 millis
- `myCanvas.after(5, someMethod)`
- See: `MovingCircle.py`

Create the Ball class

- Ball
 - attributes: color, gravity, airResistance, current location, current velocity
- Constructor needs to create a circle on the canvas, and set the appropriate attributes
- See Ball1.py

Falling Ball

- At time T we are at 100m
- Our velocity is -10m/s
- So, at time $t=1$ where are we?
- At time $t=2$ where are we?

- See `Ball2.py`

Bouncing Ball

- Everytime we hit the floor, or a wall, just change the direction of our velocity.
- if we're at the floor, start going up
- if we're at the ceiling, start going down
- if we're at the left/right ...
- See `Ball3.py`

Acceleration

- As the ball bounces, gravity needs to act on it.
- Gravity accelerates at -9.8ms^2 . So every second go 9.8m/s faster than the previous second!
- $y\text{Velocity} = y\text{Velocity} + 9.8$
- See `Ball4.py`

Fix some issues

- Make the “moves” smaller, by dividing all the velocities and times by 10
- Fix the problem that the ball bounces past the bottom of the screen
- Ball5.py
- Ball6.py --- add in lots of balls!

Design Summary

- Think about each “object” in your system
 - What behaviors should it have?
 - What information does it need to know?
What information changes from one instance of this object to the next?
- There are many books on design strategies for object oriented programming!

Extra Slides

Bouncing Ball: Physics 101

- gravity accelerates items at 9.8m/s^2
 - so every second you fall, your speed increases by 9.8m/s
- Our velocity has two components

- Assuming Θ is 30 degrees
- $\cos(\Theta) = x / 10$
- $\sin(\Theta) = y / 10$

Bouncing Ball: Physics 101

- Our velocity has two components

- Assuming Θ is 30 degrees
- $\cos(\Theta) = x / 10$
- $\sin(\Theta) = y / 10$
 - $x = 10 \cos(30) = 8.66 \text{ m/s}$
 - $y = 10 \sin(30) = 0.5 \text{ m/s}$

Bouncing Ball: Physics 101

- Our velocity has two components

- So, if our ball is travelling at 10 m/s, the y velocity is subject to gravity, but not the x. (we'll ignore wind resistance and all other factors)
- So the first second we travel 8.66 meters in X and 0.5 meters in Y

Bouncing Ball: Physics 101

- Our update function will use simulation to keep the ball moving:
 - update():

```
# If we call update every second, then the change in X and Y directions are just their
# velocity (since it's in meters/second)
deltaX = 8.66 # Velocity in X direction never changes
yVelocity = yVelocity - 9.8 # Gravity
deltaY = yVelocity

# Move the ball
self.canvas.move(self.itm, deltaX, deltaY)
```

This gives us a falling ball, how do we make it bounce?

Bouncing Ball: Physics 101

- If we hit the “floor”, change the yVelocity from positive to negative, and reduce it some (we bounce a little lower than we started)

```
# Bounce off the "floor"
```

```
if self.yLoc > self.bottomWall:
```

```
    self.yVelocity = -1 * self.yVelocity * self.bouncyness
```

```
    deltaY = self.bottomWall - self.yLoc # Make sure you're above the floor!
```

```
else:
```

```
    deltaY = int(self.yVelocity)
```

```
self.yLoc += deltaY
```

Now we bounce up and down,
what about left and right wall?

Bouncing Ball: Physics 101

- If we hit the left/right wall, just change our x direction

```
# Bounce off the "wall"
```

```
if self.xLoc > self.rightWall or self.xLoc < self.leftWall:
```

```
    self.xVelocity *= -1
```

```
deltaX = self.xVelocity/5
```

```
self.xLoc += deltaX
```

Great... but the balls should stop
not keep rolling around

Bouncing Ball: Physics 101

- If we get to a very small yVelocity, just stop bouncing and rolling.

```
# The ball isn't bouncing... stop!  
if abs(self.yVelocity) < 10 and self.yLoc >= (self.bottomWall-5):  
    self.yVelocity = 0  
    self.xVelocity = 0  
    return  
else:  
    self.yVelocity += 2 #9.8/5
```

Bouncing Ball: Physics 101

- Now it's easy to create a whole bunch of balls because they are Objects, and each will maintain it's own state (velocities)

```
for i in range(10):
```

```
    rcolor = '#%d%d%d' %(randint(0,9), randint(0,9), randint(0,9)) # Random color
```

```
    ball = Ball(randint(left,right), randint(top,bottom), randint(2,20), \
```

```
                randint(2,20), color=rcolor, \
```

```
                leftWall=left, rightWall=right, topWall=top, bottomWall=bottom)
```

```
    ball.draw(canvas)
```

```
    balls.append(ball)
```
